Abstract. In this paper, the convolutional neural network and long short-term memory (CNN-LSTM) neural network is applied to model and analyse quantitative selection and quantitative timing strategy in stock markets. Methodically, the CNN is utilized to make the quantitative stock selection strategy, and then make the quantitative timing strategy for improving the profits by using the LSTM. It is demonstrated by the experiments that the CNN-LSTM neural network model can be successfully applied to making quantitative strategy, and achieving better returns than the Benchmark index.

Keywords: Neural network model, CNN-LSTM, Quantitative selection, Quantitative timing, Stock markets, Strategy analysis.

1 Introduction

The complexity of the internal structure in stock price system and the diversity of the external factors (the national policy, the bank rate, price index, the performance of quoted companies and the psychological factors of the investors) determine the complexity of the stock market, uncertainty and difficulty of stock price forecasting task [1]. The stock market has the characteristics of high return and high risk, which has always been concerned on the analysis and forecast in the stock prices [2,3]. One of the main ideas of the quantitative strategy is to predict and judge the future price of the stock by using the trend of the stock market, and draws up the corresponding investment strategy.

A convolutional neural network (CNN) is any spatial arrangement of locally-coupled cells, where each cell is a dynamical system which has an input, an output, and a state evolving according to some prescribed dynamical laws [4]. The CNN is a mapping from input to output in essence, it can study the mapping relationship without precise mathematical expression between any input and output. As long as convolutional network training using the known pattern, network has the mapping ability between the input and output. Thus we can use CNN for stock ranker to achieve the quantitative stock selection strategy.

To achieve better returns, we adopt the recurrent neural networks (RNN) which have proved one of the most powerful models for processing sequential data. Long Short-Term Memory (LSTM) is one of the most successful RNNs architectures to fix the vanishing gradient problem in neural network [5]. LSTM introduces the memory cell, a unit of computation that replaces traditional artificial neurons in the hidden layer of the network. With these memory cells, networks are able to effectively associate memories and input remote in time, hence suit to grasp the structure of stock data dynamically over time with high prediction capacity [6]. Hence we can use LSTM to achieve the quantitative timing strategy.

The experimental results show that this CNN-LSTM neural network model can find potential rules from historical datasets, and the corresponding quantitative selection and timing strategy is valid and profitable. The rest of this paper is organized as follows. In Section 2, we give a brief review of the CNN and LSTM and CNN-LSTM framework. Section 3 presents the CNN-LSTM flow chart, and the experimental results of as well as the comparisons of the Benchmark index. Finally, we give conclusion in Section 4.

2 The CNN-LSTM neural network

2.1 CNN

For supervised classification, CNNs are among the most successful models and set the state-of-the-art result in many benchmarks [7]. Convolutional neural networks involve many more connected weights. A form of regularization is realized in the architecture, and some degree of translation invariance is provided automatically. This particular kind of neural network assumes that we wish to learn filters, in a data-driven fashion, as a means to extract features describing the inputs. The full CNN framework and formula derivation can be seen in the literatures[8].

CNNs are hierarchical models whose convolutional layers alternate with sub-sampling layers, reminiscent of simple and complex cells in the primary visual cortex[9]. The previous layer feature maps are convolved with learnable kernels, which form the output feature map through the activation function. Multiple input maps may be combined as the output with convolutions. For convenience we just introduce the convolution layer:

$$x_j^l = f\left(\sum_{i \in M_j} x_i^{l-1} * k_{ij}^l + b_j^l\right), \quad (1)$$

where M_j represents a selection of input maps.

2.2 LSTM

Recurrent neural networks have the capability to dynamically incorporate past experience due to internal recurrence [10]. RNNs can project the dynamic properties of the system automatically, so they are computationally more powerful

than feed-forward networks, and the valuable approximation results are obtained for chaotic time series prediction [11,12]. One of RNN models is long-short-term memory which works when there is a long delay, and the signals with a mixture of low and high frequency components can be able to handled. The learning process of RNN models however requires a relatively long time because there is a recurrent network architecture [13].

A schematic of the vanilla LSTM block [14] can be seen in Figure 1. It features three gates (input, forget and output), block input, a single cell (the Constant Error Carousel), an output activation function, and peephole connections. The output of the block is recurrently connected back to the block input and all of the gates. The vector formulas for LSTM layer forward pass are given in [14]. In order to facilitate your understanding, just listed below:

Fig. 1. Detailed Long Short-Term Memory block as used in the hidden layers of a recurrent neural network.

$$z^t = g(W_z x^t + R_z y^{t-1} + b_z) \quad \text{block input} \quad (2)$$

$$i^t = \sigma(W_i x^t + R_i y^{t-1} + p_i \odot c^{t-1} + b_i) \quad \text{input gate} \quad (3)$$

$$f^t = \sigma(W_f x^t + R_f y^{t-1} + p_f \odot c^{t-1} + b_f) \quad \text{forget gate} \quad (4)$$

$$c^t = i^t \odot z^t + f^t \odot c^{t-1} \quad \text{cell state} \quad (5)$$

$$o^t = \sigma(W_o x^t + R_o y^{t-1} + p_o \odot c^t + b_o) \quad \text{output gate} \quad (6)$$

$$y^t = o^t \odot h(c^t) \quad \text{block output} \quad (7)$$

where x^t is the input vector at time t , the W are input weight matrices, the R are square recurrent weight matrices, the p are peephole weight vectors and b are bias vectors. Functions σ , g and h are point-wise non-linear activation functions: *logistic sigmoid* $\left(\frac{1}{1+e^{-x}}\right)$ is used for as activation function of the gates and *hyperbolic tangent* is used as the block input and output activation function. The point-wise multiplication of two vectors is denoted as \odot .

2.3 The CNN-LSTM framework

The details of the CNN-LSTM framework are as follows:

Algorithm 1 The CNN-LSTM framework

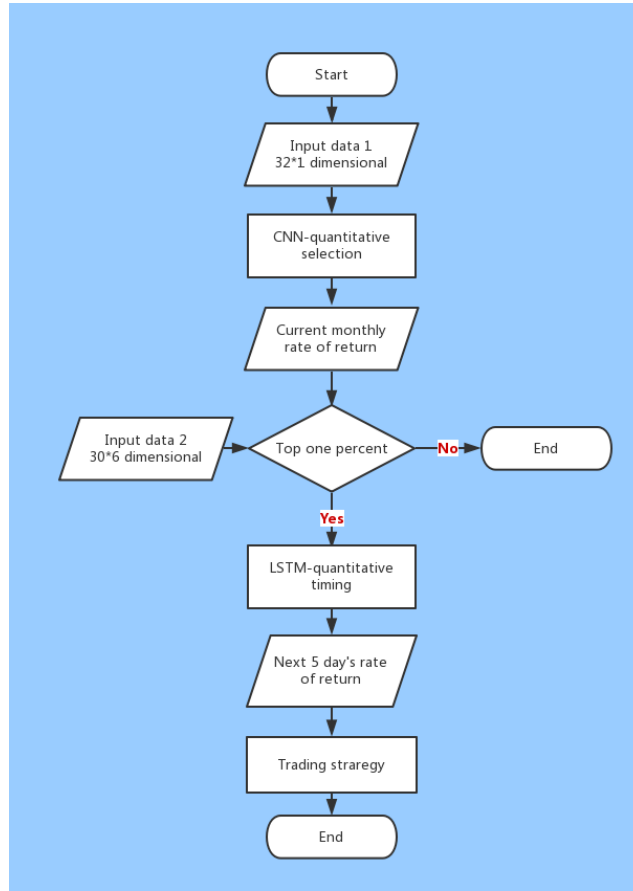

- 1: Initialization of parameters and data.
 - 2: **repeat**
 - 3: **repeat**
 - 4: CNN-quantitative selection step:
 input: 32*1 dimensional matrix, i.e. the monthly rates of return from the first 13 month to the first 2 month and the daily rates of return from the first 20 day to the first 1 day.
 - 5: **until** Either the component remains the same in the previous iteration, or the iterations reach certain threshold.
 - 6: Output the predicted current monthly rate of return.
 - 7: **until** All shares are traversed in the A stock market.
 - 8: Select the top one percent stock in the CNN step output.
 - 9: **repeat**
 - 10: **repeat**
 - 11: LSTM-quantitative timing step:
 input: 30*6 dimensional matrix, i.e. before 30 days' features: ['open', 'close', 'high', 'low', 'amount', 'volume'].
 - 12: **until** Either the component remains the same in the previous iteration, or the iterations reach certain threshold.
 - 13: Output the predicted next 5 days' rate of return: 1 if positive rate, otherwise -1.
 - 14: **until** All selected shares are traversed.
 - 15: Output the current monthly total return.
-

3 Experiment Results

We implement CNN-LSTM neural network model for quantitative selection and quantitative timing strategy on the training dataset, and verify its performance on the test dataset. We are exploring a parallel implementation of the learning algorithm that could be run on GPUs. Our experiments are implemented in the Linux system (Ubuntu 16.04.2 LTS) with GPU (device 0: GeForce), and 16.00GB RAM with running Python 2.7 source codes.

This approach should lead to a substantial decrease in training time as the algorithm can take advantage of parallelization at the data-level (since it uses mini-batches) as well as at the network layer level. Alternatively, a more straightforward approach would be to retrain the classifier each month, but update the LSTM more frequently in order to improve profits which are infinitely close to local optimization.

The details of CNN-LSTM flow chart and parameters are described in the Figure 2 and in the Table 1 as follows:

**Fig. 2.** CNN-LSTM flow chart.**Table 1.** The parameters for CNN-LSTM.

Parameters	CNN	LSTM
Input Layer	1	1
Conv/LSTM hidden Layer	2	1
FCN hidden Layer	2	1
Output Layer	1	1
Epoch	500	100
Activation	ReLU,Tanh	Tanh
Weight	Normal(0,1)	Normal(0,1)
Optimizer	Adam	Adam
Learning Rate	0.001	0.001
Objective function	cross-entropy	cross-entropy

Data setting and preprocessing of CNN-LSTM neural network are described in the framework. We did z-score standardization of data when necessary. Time span of training data is from 2007-1-1 to 2013-12-31, and time span of testing data is from 2014-1-1 to 2017-3-31. Only the features which are to be fed to the neural network are chosen, trained for prediction assigning random biases and weights. In our CNN-LSTM model the LSTM part is composed of a sequential layers followed by 1 LSTM layer and dense layer with Tanh activation.

Over fitting of neural networks is one of the most difficult things to avoid in training neural networks. Over fitting means that the model performs well in training data, but for the other data the predictor effect is poor. The reason is usually "rote" data and noises, which leads to complicated model. To avoid over-fitting of the model, the dropout parameter is added to the CNN-LSTM model and the regularization term is applied to the weight. Dropout refers to drop some features randomly to improve the robustness of the model. Regularization refers to add an L2 norm in the calculation of the loss function, so that some of the weight value close to 0 to avoid forced adaptation for each feature. Then it improves the robustness, also has the effect of feature choice.

When the LSTM predictive value is equal to 1, we buy and hold 5 days, and if previous positions, update the number of held days as 5 and continue held. When the LSTM predictive value is equal -1, it continues if short positions, and if already held shares, the number of held days will be decreased by one, and if the number of held days is equal to 0, we will sell the share.

Fig. 3. The net value curves of CNN-LSTM and Benchmark.

Table 2. The comparison of the results

	CNN-LSTM Benchmark	
Annualized rate of return	0.339	0.135
Maximum retracement	0.235	0.417

We compare the net value, the rate of return and the maximum retracement of our CNN-LSTM model with the Benchmark index respectively in the Figure 3 and Table 2.

The net value curves demonstrate a significant increase in the performances qualitatively. During the stock market crash, the maximum retracement of CNN-LSTM is tolerable. The annualized rate of return using our CNN-LSTM neural network model is 2.5 times as large as the annualized rate of return using Benchmark index. Meanwhile, the maximum retracement of CNN-LSTM neural network model is 56 percent of the maximum retracement of Benchmark index. The experiments fully illustrate our model is efficient and the investment return is impressive, and verify the robustness and practicability of the algorithm as well.

4 Conclusion

We have successfully applied the CNN-LSTM neural network to modeling and making the quantitative stock selection and timing strategy. The experiment results demonstrate that LSTM neural network predicts a high accuracy in future stock prices and the predicting outcomes are used as timing signals, which significantly improve the retracement of the CNN stock selection model in the backtesting stage. As good quantitative strategy, the CNN-LSTM neural network model is feasible, robust and highly profitable.
